$k$-trees, $k$-frames, shells and independence polynomials

ABSTRACT

Much of what is known about trees extends smoothly to $k$-trees. Some fairly recent results of this type, concerning independence polynomials, will be presented. We discuss the 'shell' of a $k$-tree, corresponding to the line graph of a tree, and some steps are taken toward a possible characterization of shells. A new class of graphs, the $k$-frames will be defined, generalizing the $k$-trees. In each of these classes of graphs, the problem of characterizing the well-covered graphs will be discussed. This is joint work with John Estes, Wanda Payne, Lanzhen Song, Bing Wei and others.
